

# Equivariant cohomology for c-symplectic spaces

Sergio Chaves

November 6, 2019

Following [Borel, 1960], let  $G$  be topological group,  $EG \rightarrow BG$  a universal principal bundle for  $G$  and let  $X$  be a topological space with a continuous action of  $G$ , or a  $G$ -space. The equivariant cohomology of  $X$ , denoted by  $H_G^*(X; R)$ , is the cohomology of  $H^*(X_G; R)$  where  $X_G = (X \times EG)/G$  is the Borel construction of  $X$ . This object inherits a canonical structure as a module over  $H^*(BG; R)$ . We say that  $X$  is  $G$ -equivariantly formal if  $H_G^*(X; R)$  is a free module over  $H^*(BG; R)$ .

## 1 Equivariant cohomology for the real locus of symplectic manifolds

The  $G$ -equivariant cohomology of a  $G$ -space  $X$  is closely related to the topology of its fixed point set  $X^G$ . This situation has appeared in more specific contexts such as the cohomology of compact symplectic manifolds; in fact, following Atiyah [Atiyah, 1982, Thm. 1], and extending Frankel's results in Kähler manifolds [Frankel, 1959, §4]. we cite the following theorem.

**Theorem 1.1.** *Let  $M$  be a compact symplectic manifold with a Hamiltonian action of a torus  $T$ . Then there is an additive isomorphism*

$$H^*(M; k) \cong \bigoplus_{i=1}^m H^{*-d_i}(F_i; k)$$

where  $F_i$ ,  $i = 1, \dots, n$  are the connected components of  $M^T$ ,  $d_i$  is the Bott-Morse index of  $F_i$ ; that is,  $d_i$  is the number of negative eigenvalues of the Hessian matrix associated to the critical submanifold  $F_i$  under the Morse-Bott function  $f = \|\mu\|^2$ . Here  $\mu$  denotes the moment map associated to the torus action.

This isomorphism is actually extended to the case of  $T$ -equivariant cohomology; namely,

$$H_T^*(M; \mathbb{R}) \cong \bigoplus_{i=1}^N H_T^{*-d_i}(F_i; \mathbb{R}) \tag{1.1.1}$$

as shown by Kirwan in [Kirwan, 1984, §5] following Atiyah-Bott [Atiyah and Bott, 1984, Thm. 3.5]. In particular, Theorem 1.1 implies that the Betti sum of  $M$  and  $M^T$  are the same and it follows that  $M$  is  $T$ -equivariantly formal over  $\mathbb{R}$ .

Motivated by the case where  $M$  is a complex projective space and the complex conjugation  $\tau : M \rightarrow M$  is an anti-symplectic involution (i.e.  $\tau^*\omega = -\omega$ , where  $\omega$  denotes the symplectic form of  $M$ ) and compatible with the torus action, Duistermaat [Duistermaat, 1983, Thm. 3.1] proved an analogous version of Theorem 1.1 for the fixed point subspace  $M^T$ , commonly known as the *Real Locus of  $M$* .

**Theorem 1.2.** *Let  $(M, \omega)$  be a symplectic manifold with a Hamiltonian action of a torus  $T$  and a compatible anti-symplectic involution  $\tau$ . There is an additive isomorphism*

$$H^*(M^\tau; \mathbb{F}_2) = \bigoplus_{i=1}^N H^{*-d_i} (F_i^\tau; \mathbb{F}_2)$$

and  $b(M^\tau) = b(M^\tau \cap M^T)$ , where  $M^T = \bigcup_{i=1}^m F_i$ .

Furthermore, in [Biss et al., 2004, Thm. A], an equivariant version of Theorem 1.2 was proved by Biss-Guillemin-Holm. Explicitly, the action of  $T$  on  $M$  induces an action of the subgroup  $T_2 = \{g \in T : g^2 = 1\}$  on  $M^\tau$  and the equivariant cohomology satisfies,

$$H_{T_2}^*(M^\tau; \mathbb{F}_2) \cong \bigoplus_{i=1}^N H_{T_2}^{*-d_i} (F_i^\tau; \mathbb{F}_2) \quad (1.2.1)$$

as  $H^*(BT_2; \mathbb{F}_2)$ -modules. They also showed that  $b(M^\tau) = b(M^\tau \cap M^{T_2}) = b((M^\tau)^{T_2})$ . In particular, this implies that  $M^\tau$  is  $T_2$ -equivariantly formal over  $\mathbb{F}_2$ .

*Remark 1.3.* When  $M$  is a symplectic manifold with a Hamiltonian action of a torus  $T$  and a compatible anti-symplectic involution  $\tau$ , similar to Chapter 4, we have an induced action of  $G = T \rtimes \mathbb{Z}/2$  and  $M^G = (M^\tau)^T = M^\tau \cap M^T$ .

Now we are interested in relating the  $T$ -equivariant cohomology of  $M$  with the  $T_2$ -equivariant cohomology of  $M^\tau$ . First, it can be shown that a symplectic manifold  $M$  with an action of a torus  $T$  is equivariantly formal if and only if the  $T$ -action is Hamiltonian (see Corollary 2.7 below); therefore, combining Theorems 1.1, 1.2 and 1.2.1 we can state the following theorem.

**Theorem 1.4.** *Let  $M$  be a symplectic manifold with an action of a torus  $T$  and a compatible involution  $\tau$ . If  $M$  is  $T$ -equivariantly formal over  $\mathbb{R}$ , then the real locus  $M^\tau$  is  $T_2$ -equivariantly formal over  $\mathbb{F}_2$ .*

If  $M$  is a complex projective space, we have that  $M$  satisfies Theorem 1.4 and also  $b(M)$  and  $b(M^\tau)$  have the same Betti sum; this implies that  $M$  is also  $\tau$ -equivariantly formal. However, the next example exhibits a symplectic manifold  $M$  where Theorem 1.4 applies, but  $M$  is not  $\tau$ -equivariantly formal.

**Example 1.5.** Consider the symplectic manifold  $(S^2, \omega)$  where  $\omega \in H^2(S^2)$  is a generator. Let  $T = S^1$  act on  $S^2$  as the rotation along the  $z$ -axis, set  $(M, \gamma) = (S^2 \times S^2, p_1^* \omega - p_2^* \omega)$  where  $p_i: M \rightarrow S^2$  is the projection onto the  $i$ -th factor. Let  $\tau: M \rightarrow M$  be the involution given by  $\tau(x, y) = (y, x)$ , then  $\tau$  is an anti-symplectic involution; and consider the action of  $T$  on  $M$  given by  $g \cdot (x, y) = (g \cdot x, g^{-1} \cdot y)$ , the action is compatible with the involution and therefore, from Theorems 1.1 and 1.2,  $H_T^*(M; \mathbb{R})$  is free over  $H^*(BT; \mathbb{R})$  and  $H_{T_2}^*(Y; \mathbb{F}_2)$  is free over  $H^*(BT_2; \mathbb{F}_2)$  where  $Y = M^\tau \cong S^2$  and  $T_2$  is the 2-torus in  $T$ . This also follows from the Betti sum criteria; namely,  $M^T$  consist of 4-points, and thus  $b(M) = b(M^T) = 4$ . Also,  $Y^{T_2}$  consists of two points and thus  $b(Y) = b(Y^{T_2}) = 2$ ; however,  $b(Y) < b(M)$  and thus the equivariant cohomology  $H_{\mathbb{Z}/2}^*(M; \mathbb{F}_2)$  is not free over  $H^*(B\mathbb{Z}/2; \mathbb{F}_2)$  where the action of  $\mathbb{Z}/2$  on  $M$  is the one given by the involution  $\tau$ .

On the other hand, we immediately have a condition for  $M$  being  $\tau$ -equivariantly formal.

**Proposition 1.6.** *Let  $M$  be a symplectic manifold with a Hamiltonian action of a torus  $T$  and a anti-symplectic involution  $\tau$ . Then  $M$  is  $\tau$ -equivariantly formal over  $\mathbb{F}_2$  if and only if  $b(M) = b(M^H)$  where  $H$  is the 2-subtorus in  $G = T \rtimes \mathbb{Z}/2$ . The latter acts on  $M$  via the induced action of  $T$  and  $\tau$ .*

By Proposition 1.6, it is enough to assume that  $X$  is  $T$ -equivariantly formal for  $X^\tau$  to be  $T_2$ -equivariantly formal in the symplectic setting. Now in the most general possible case, we have the following question.

**Question 1.7.** *Let  $X$  be a  $T$ -space together with a compatible involution  $\tau$ . Assume that  $b(X) < \infty$  and  $H_T^*(X; \mathbb{F}_2)$  is a free  $H^*(BT; \mathbb{F}_2)$ -module. Is  $H_{T_2}^*(X^\tau; \mathbb{F}_2)$  a free  $H^*(BT_2; \mathbb{F}_2)$ -module where the action of the 2-torus  $T_2 \subseteq T$  on  $X^\tau$  is the one induced by the action of  $T$  on  $X$ ?*

Without extra assumptions on the space, a negative answer can be given as we will describe in the next proposition.

**Proposition 1.8.** *There exists a manifold  $X$  with an action of  $T = S^1$  and a compatible involution  $\tau$  such that  $X$  is  $T$ -equivariantly formal and the real locus  $X^\tau$  is not equivariantly formal with respect to the induced action of the 2-torus subgroup  $T_2 \subseteq T$ .*

*Proof.* let  $X = \{(u, z) \in \mathbb{C} \times \mathbb{R} : |u|^2 + |z|^2 = 1\} = S^2$ , let  $T = S^1$  act on  $X$  by  $g \cdot (u, z) = (gu, z)$ ; more precisely, by scalar multiplication in the first factor. Let  $\tau$  be the involution  $\tau(u, z) = (\bar{u}, -z)$  which is compatible with the torus action. Notice that  $X^T = \{(0, 1), (0, -1)\} \cong S^0$  and  $X^\tau = \{(-1, 0), (1, 0)\} \cong S^0$ . Therefore, the action of  $T_2$  on  $X^\tau$  is the multiplication by  $\pm 1$  and thus it is a free  $T_2$ -space, this implies that its  $T_2$ -equivariant cohomology is not free over  $H^*(BT_2)$ . On the other hand,  $H_T^*(X)$  is a free  $H^*(BT)$ -module since  $X$  and  $X^T$  have the same Betti sum.  $\square$

One of the main issues of this example is that  $X^G = \emptyset$ , even assuming  $X^G \neq \emptyset$  a counterexample of question 1.7 can be found and its construction is motivated by [Su, 1964, Sec. 5]. First we recall the following well known construction of topological spaces.

**Definition 1.9.** Let  $f : X \rightarrow Y$  be a  $G$ -map between  $G$ -spaces  $X$  and  $Y$ . The mapping cylinder is defined as the  $G$ -space  $M_f = (X \times [0, 1]) \sqcup Y / \sim$  where  $(x, 1) \sim f(x)$ , with the action given by  $g \cdot (x, t) = (gx, t)$  for  $(x, t) \in X \times [0, 1]$  and the regular action on  $Y$ ; notice that it is well defined at the points of the form  $(x, 1)$  since  $f$  is a  $G$ -map.

The space  $M_f$  is  $G$ -homotopic to  $Y$ , and therefore  $H^*(M_f) \cong H^*(Y)$ . Also, the fixed point subspace  $(M_f)^G \cong M_{f^G}$  where  $f^G : X^G \rightarrow Y^G$ . Now let  $g : X \rightarrow Z$  be a  $G$ -map and  $M_g$  the respective mapping cylinder, then the space  $M_{f,g} = M_f \cup_{X \times \{0\}} M_g$  has cohomology groups fitting in the long exact sequence

$$0 \rightarrow H^0(M_{f,g}) \rightarrow H^0(Y) \oplus H^0(Z) \rightarrow H^0(X) \rightarrow H^1(M_{f,g}) \rightarrow \dots$$

following from the Mayer-Vietoris long exact sequence. Moreover,  $M_{f,g}$  becomes a  $G$ -space and  $(M_{f,g})^G \cong M_{f^G, g^G}$ . In particular, we have

**Proposition 1.10.** *Let  $m, n, r$  be different integers,  $h : S^m \rightarrow S^n$  a map between spheres and consider  $f = h \times id : S^m \times S^r \rightarrow S^n \times S^r$  and  $g : S^m \times S^r \rightarrow S^m$  the projection. Then  $H^*(M_{f,g})$  is free over  $\mathbb{Z}/2$  where a copy of  $\mathbb{Z}/2$  happens in degree  $0, n, m+r+1, n+r$  and it is zero otherwise. In particular,  $b(M_{f,g}) = 4$ .*

**Example 1.11.** Let  $X = S^3 \subseteq \mathbb{C}^2$ ,  $Y = S^5 \subseteq \mathbb{C}^3$  and  $Z = S^9 \subseteq \mathbb{C}^4$ . Let  $T = S^1$  act on  $X$  and  $Y$  by scalar multiplication on the first component, respectively, and let  $T$  act on  $Z$  by scalar multiplication on the first and second component and trivially otherwise. Then  $X^T = S^1$ ,  $Y^T = S^3$  and  $Z^T = S^5$ . Let  $\tau$  act on  $X$  and  $Y$  as the complex conjugation on the first component respectively, and on  $Z$  as the complex conjugation on the first and second component and multiplication by  $-1$  on the other components. Then  $X^\tau = S^2$ ,  $Y^\tau = S^4$  and  $Z^\tau = S^1$ . Note that the induced action of  $T_2 \subseteq T$  is free on  $Z^\tau$ .

Let  $f : X \times Z \rightarrow Y \times Z$  be the map  $i \times id$  where  $i$  is the inclusion  $i(u, z) = (u, z, 0)$ , and  $g : X \times Z \rightarrow X$  the projection. Consider the  $T$ -space  $M = M_{f,g}$  and the induced action of  $\tau$  on  $M$  becomes a compatible involution. Then  $b(M) = b(M^T) = b(M^\tau) = 4$  from Proposition 1.10, but  $b(M^G) = b((M^\tau)^{T_2}) = 2$ .

**Example 1.12.** Let  $X = S^3$ ,  $Y = S^2$  and  $h : X \rightarrow Y$  be the Hopf map. This map can be explicitly presented as  $h(u, z) = (2u\bar{z}, |u|^2 - |z|^2)$  where  $S^3$  is seen as the unit sphere in  $\mathbb{C}^2$  and  $S^2$  as the unit sphere in  $\mathbb{C} \times \mathbb{R}$ . Let  $T = S^1$  act on  $S^3$  and  $S^2$  as the complex multiplication in the first component respectively, and  $\tau$  be the involution on  $S^3$  and  $S^2$  given by the complex conjugation in the first component respectively. Then  $\tau$  is compatible with the torus action and  $X^T \cong S^1$ ,  $X^\tau \cong S^2$ ,  $Y^T \cong S^0$  and  $Y^\tau \cong S^1$ . Now let  $Z = S^5$  be the unit sphere in  $\mathbb{C}^3$ , let  $T$  act on  $Z$  by multiplication in the first component and  $\tau$  be the involution on  $Z$  given by the complex conjugation in the first component, and multiplication by  $-1$  in the second and third component; then  $Z^T \cong S^3$  and  $Z^\tau \cong S^0$ , notice that the action of the 2-torus  $T_2 \subseteq T$  on  $Z^\tau$  is free.

Let  $M = M_{f,g}$  be the construction of Proposition 1.10, then  $b(M) = b(M^T) = b(M^\tau) = 4$  and thus  $M$  is  $T$ -equivariantly formal; nevertheless,  $M^\tau$  is not  $T_2$ -equivariantly formal since  $b((M^\tau)^{T_2}) = 2 < b(M^\tau)$ .

These examples provide a negative solution for Question 1.7 with non-empty common fixed points of both  $T$  and  $\tau$ . Summarizing we get.

**Proposition 1.13.** *There is a topological space  $M$  with an action of a torus  $T$  and a compatible involution  $\tau$  such that  $M^G \neq \emptyset$ ,  $M$  is  $T$ -equivariantly formal and  $\mathbb{Z}/2$ -equivariantly formal, but the real locus  $M^\tau$  is not  $T_2$ -equivariantly formal with respect to the induced action of the 2-torus  $T_2 \subseteq T$  on  $M^\tau$ .  $\square$*

## 2 Cohomologically symplectic spaces

**Definition 2.1.** Let  $M$  be a  $\mathbb{k}$ -Poincaré duality space with formal dimension  $2n$ . We say that  $M$  is a  $c$ -symplectic space (cohomologically symplectic), if there is a class  $\omega \in H^2(M; \mathbb{k})$  such that  $\omega^n \neq 0$ .

Notice that any compact symplectic manifold is a  $c$ -symplectic space; however, there exists  $c$ -symplectic spaces which do not admit a symplectic structure. For instance, the connected sum  $\mathbb{C}P^2 \# \mathbb{C}P^2$  is  $c$ -symplectic but it does not admit a symplectic form [Audin, 1991, Prop 1.3.1].

**Definition 2.2.** A  $c$ -symplectic space  $M$  satisfies the weak Lefschetz condition if the multiplication by  $\omega^{n-1}$  induces an isomorphism  $H^1(M; \mathbb{k}) \cong H^{2n-1}(M; \mathbb{k})$ . Moreover, if the multiplication by  $\omega^r$  induces an isomorphism  $H^{n-r}(M; \mathbb{k}) \cong H^{n+r}(M; \mathbb{k})$  for  $r = 1, \dots, n-1$ . we say that  $M$  satisfies the strong Lefschetz condition. Since any Kähler manifold satisfies the strong Lefschetz condition, we define analogously the cohomological version. More precisely, a  $c$ -symplectic space satisfying the strong Lefschetz condition is called a  $c$ -Kähler (cohomologically-Kähler) space.

An important property of the  $c$ -Kähler spaces is a condition over its Betti numbers, as we remark in the following result.

**Proposition 2.3.** *Let  $M$  be a  $c$ -Kähler space, then the odd Betti numbers  $b_{2k+1}(M)$  are even.*

*Proof.* Let  $s = 2k + 1$ . From a standard result in symplectic linear algebra, it is enough to show that  $H^s(M)$  admits a non-degenerate skew-symmetric bilinear form. Let  $1 \leq r \leq n-1$  be such that  $s = n+r$  or  $s = n-r$ , assume without loss of generality the latter. Consider the isomorphism  $\phi : H^s(M) \rightarrow H^{2n-s}(M)$  given by multiplication by  $\omega^r$  from the strong Lefschetz condition. Consider the non degenerate pairing given by Poincaré duality  $\mu : H^s(M) \times H^{2n-s}(M) \rightarrow \mathbb{k}$ . Then the bilinear form on  $H^s(M)$  given by  $\Omega(a, b) = \mu(a, \phi^{-1}(b))$  is a non-degenerate skew-symmetric form and thus  $H^s(M)$  is an even-dimensional vector space.  $\square$

**Definition 2.4.** Let  $G$  be a torus if  $\mathbb{k} = \mathbb{Q}$  or a  $p$ -torus if  $\mathbb{k} = \mathbb{F}_p$ . An action of  $G$  on  $M$  is said to be  $c$ -Hamiltonian (cohomologically Hamiltonian) if  $\omega \in \text{Im}(i^* : H_G^*(M; \mathbb{k}) \rightarrow H^*(M; \mathbb{k}))$ .

**Proposition 2.5.** *Let  $M$  be a  $c$ -symplectic space with an action of a torus  $T$ . Assume that  $M$  satisfies the weak Lefschetz condition and that  $M^T \neq \emptyset$ , then the action is  $c$ -Hamiltonian.*

*Proof.* We can assume that  $T$  is a circle. Consider the spectral sequence associated to the fibration  $M \rightarrow M_T \rightarrow BT$ , write  $d_2(\omega) = x \cdot c \in H^1(M) \otimes H^2(BT)$  where  $c \in H^2(BT)$  is a generator. Since  $M$  is a Poincare duality space and  $M^T \neq \emptyset$ ,  $\omega^n \in \text{Im}(H_T^*(M) \rightarrow H^*(M))$  and thus  $0 = d_2(\omega^n) = n\omega^{n-1}x \cdot c$ . From the weak Lefschetz condition we get that  $x = 0$  and so  $d_2(\omega) = 0$ . Since this is the only possible non-zero differential on  $\omega$ , we get  $\omega \in \text{Im}(H_T^*(M) \rightarrow H^*(M))$ .  $\square$

In the case of symplectic manifolds, the Hamiltonian torus action and  $c$ -Hamiltonian torus action are the same. This can be shown using the Cartan model for equivariant cohomology. [Mukherjee, 2005, Prop. 1.5.6]

**Theorem 2.6.** *Let  $M$  be a symplectic manifold with an action of a torus  $T$ . The action is Hamiltonian if and only if it is  $c$ -Hamiltonian.*

From Theorem 1.1 we get that a Hamiltonian torus action is equivariantly formal. On the other hand, if  $M$  is  $T$ -equivariantly formal, the map  $H_T^*(M) \rightarrow H^*(M)$  is surjective and thus the action is  $c$ -Hamiltonian. Therefore, from 2.6 we obtain the following result.

**Corollary 2.7.** *Let  $M$  be a symplectic manifold with an action of a torus  $T$ . The action is Hamiltonian if and only if  $M$  is  $T$ -equivariantly formal.*

The following lemma, whose proof requires standard results in algebraic topology, will allow us to construct further examples.

**Lemma 2.8.**

- (a) *Let  $M$  and  $N$  be connected  $\mathbb{k}$ -orientable manifolds of the same dimension  $n$ . Then  $b_i(M\#N) \cong b_i(M) + b_i(N)$  for  $i \neq 0, n$  and  $b_0(M) = b_n(M) = 1$ .*
- (b) *Let  $M$  be a connected manifold of dimension  $n \geq 2$ . Denote by  $\widetilde{M}$  the manifold obtained by “attaching a handle” on  $M$ ; more precisely, remove two open sets  $U, V \cong D^n$  of  $M$  and then glue a cylinder  $S^{n-1} \times I$  along the common boundary  $S^{n-1} \sqcup S^{n-1}$ . Then  $b_i(\widetilde{M}) = b_i(M)$  for  $i \neq n-1, 1$ ; moreover, when  $n > 2$  we have that  $b_j(\widetilde{M}) = b_j(M) + 1$  for  $j = 1, n-1$  and if  $n = 2$  we have  $b_1(\widetilde{M}) = b_1(M) + 2$ .*

*Proof.* Let  $C$  denote the gluing cylinder in both cases. To prove (a), observe that collapsing  $C$  into a point we get an isomorphism  $H^*(M\#N, C) \cong H^*((M\#N)/C, C) \cong \widetilde{H}^*(M \vee N)$ . Using the cohomology long exact sequence for the pair  $(M\#N, C)$  and that  $H^*(C) = H^*(S^{n-1})$  we have immediately that  $\widetilde{H}^i(M\#N) \cong \widetilde{H}^i(M \vee N)$  for  $i \neq n, n-1$ . To compute the remaining degrees, we look at the short exact sequence

$$0 \rightarrow H^{n-1}(M \vee N) \rightarrow H^{n-1}(M\#N) \rightarrow H^{n-1}(S^{n-1}) \rightarrow H^n(M \vee N) \rightarrow H^n(M\#N) \rightarrow 0$$

where the map  $H^n(M \vee N) \rightarrow H^n(M\#N)$  coincides with the surjective map  $\mathbb{k} \otimes \mathbb{k} \rightarrow \mathbb{k}$  as  $M, N$  and  $M\#N$  are  $\mathbb{k}$ -orientable and thus  $H^{n-1}(M \vee N) \cong H^{n-1}(M\#N)$ . To prove (b) we use the Mayer-Vietoris long exact sequence. We write  $\widetilde{M} = N \cup S$  where  $N$  is homeomorphic to  $M$  with two discs removed  $U$  and  $V$ , and  $S \cong S^{n-1}$ ; also we have that the intersection  $N \cap S \cong S^{n-1} \sqcup S^{n-1}$ . Therefore, the Mayer-Vietoris long exact sequence yields

$$\begin{aligned} 0 \rightarrow \mathbb{k} \rightarrow H^1(\widetilde{M}) \rightarrow H^1(N) \oplus H^1(S^{n-1}) \rightarrow H^1(S^{n-1}) \oplus H^1(S^{n-1}) \rightarrow \dots \\ \dots \rightarrow H^{n-1}(\widetilde{M}) \rightarrow H^{n-1}(N) \oplus H^{n-1}(S^{n-1}) \rightarrow H^{n-1}(S^{n-1}) \oplus H^{n-1}(S^{n-1}) \end{aligned}$$

$$\rightarrow H^n(\widetilde{M}) \rightarrow H^n(N) \rightarrow 0$$

Therefore,  $b_i(\widetilde{M}) = b_i(N)$  for  $i \neq 1$ ,  $b_1(\widetilde{M}) = b_1(N) + 1$  and  $b_n(\widetilde{M}) = 1$ . It only remains to compute the Betti numbers of  $N$ . To do so, we use again the Mayer-Vietoris sequence for the decomposition  $M = N \cup W$  where  $W = U \cup V \cong D^n \sqcup D^n$ . In this case, the sequence give us  $b_i(N) = b_i(M)$  for  $i \neq n-1, n$ ,  $b_{n-1}(N) = b_{n-1}(M) + 1$  and  $b_n(N) = 0$ . The statement of the lemma follows by combining the results from the two sequences discussed above.  $\square$

If  $M$  is a c-symplectic space which is  $T$ -equivariantly formal, then the action is automatically c-Hamiltonian. However, if  $M$  admits a c-Hamiltonian action of a torus  $T$ , it is not necessarily  $T$ -equivariantly formal; as we state in the following proposition.

**Proposition 2.9** (C. Allday [Allday, 1998]). *There exist a c-symplectic space  $M$  satisfying the weak Lefschetz condition together with a c-Hamiltonian action of a circle  $T$  and  $b(M^T) < b(M)$ . Thus  $M$  is not  $T$ -equivariantly formal.*

*Proof.* Let  $T = S^1$  act freely on  $X = S^3 \times S^3$ . By the equivariant tubular neighborhood consider a tube  $U = S^1 \times D^5$  around an orbit where  $T$  acts by multiplication on the first factor. Remove the interior of the tube and glue  $D^2 \times S^4$ , where  $T$  acts by rotations on the first factor. Call the resulting manifold  $N$ , then  $N$  is a  $T$ -space where  $N^T = S^4$ . Using the Mayer-Vietoris long exact sequence, we obtain that the Betti numbers of  $H^*(N; \mathbb{Q})$  are 1, 0, 1, 2, 1, 0, 1 in degree 0, 1,  $\dots$ , 6 respectively; in fact, let  $N_0 = X \setminus U$  which is homeomorphic to  $S^3 \times S^3$  with an orbit removed around a chosen point. Let  $V \cong S^1 \times D^5$  be such that  $X = N_0 \cup V$  and  $N_0 \cap V \cong S^1 \times (D^5 \setminus \{0\})$  which has the homotopy type of  $S^1 \times S^4$ . Applying the Mayer-Vietoris long exact sequence for such decomposition we get that  $H^*(N_0)$  has dimension 1, 0, 0, 2, 1, 0, 0 in degree 0, 1,  $\dots$ , 6 respectively. Now,  $N$  is constructed by gluing  $N_0$  and  $D^2 \times S^4$  along the common boundary  $S^1 \times S^4$ , this provides a decomposition of  $N$  into open sets  $U \subseteq V$  such that  $U \cong N_0$ ,  $V \cong S^4$ ,  $U \cup V = N$  and  $U \cap V \cong S^1 \times S^4$ . From the Mayer-Vietoris long exact sequence the Betti numbers of  $H^*(N; \mathbb{Q})$  are the ones stated above.

Now let  $T$  act on  $\mathbb{C}P^3$  by  $g \cdot [z_0 : z_1 : z_2 : z_3] = [gz_0 : z_1 : z_2 : z_3]$ , so the fixed point subspace is homeomorphic to  $p \sqcup \mathbb{C}P^2$  where  $p = [1 : 0 : 0 : 0]$ . Let  $M = N \# \mathbb{C}P^3$  be the equivariant connected sum formed by removing  $T$ -invariant discs around fixed points of  $p \in N^T = S^4 \subseteq N$  and  $y \in (\mathbb{C}P^3)^T = \mathbb{C}P^2 \subseteq \mathbb{C}P^3$ ; the existence of the  $T$ -invariant discs follows from the Equivariant tubular neighborhood theorem (Theorem ??). This implies then that  $b(M) = 8$ . Notice that  $M^G \cong p \cup (S^4 \# \mathbb{C}P^2) \cong p \cup \mathbb{C}P^2$ ; moreover, the non-trivial form  $\omega \in H^2(\mathbb{C}P^3; \mathbb{Q})$  induces a non trivial form  $\tilde{\omega} \in H^2(M; \mathbb{Q})$  such that  $\tilde{\omega}^3 \neq 0$ , so  $M$  is a c-symplectic space. Moreover, since  $\mathbb{C}P^3$  is  $T$ -equivariantly formal, the lifting of the class  $\omega$  to  $H_T^*(\mathbb{C}P^3; \mathbb{Q})$  induces a lifting of  $\tilde{\omega}$  to  $H_T^*(M; \mathbb{Q})$  and thus the action of  $T$  on  $M$  is c-Hamiltonian. However, since  $b(M^T) = 4 < b(M) = 8$ ,  $M$  is not  $T$ -equivariantly formal and therefore Theorem 1.1 does not hold in the case of c-symplectic spaces.  $\square$

Even though we may consider formal Hamiltonian torus action on c-symplectic spaces, Question 1.7 in the setting of c-symplectic spaces does not have a positive solution. The example will be constructed in a similar fashion as in Proposition 2.9.

**Proposition 2.10.** *There exists a c-symplectic space  $M$  with a torus action of  $T$  and a compatible c-antisymplectic involution  $\tau$  such that  $M$  is  $T$ -equivariantly formal over  $\mathbb{Q}$  and the real locus  $M^\tau$  is not equivariantly formal over  $\mathbb{F}_2$  with respect to the induced action of the 2-torus subgroup  $T_2 \subseteq T$ .*

*Proof.* Let  $T = S^1$ , consider the  $T$ -action on  $S^3 \subseteq \mathbb{C} \times \mathbb{C}$  given by  $g \cdot (u, z) = (gu, z)$  and the involution  $\tau$  defined as  $\tau(u, z) = (\bar{u}, -z)$ , then  $\tau$  is compatible with the  $T$ -action and we have an induced action of  $G = T \rtimes \mathbb{Z}/2$ ;

moreover,  $(S^3)^T \cong S^1 \subseteq \{0\} \times \mathbb{C}$  and  $(S^3)^\tau \cong S^0 \subseteq \mathbb{C} \times \{0\}$ . Let  $X = S^3 \times S^3$  be the  $G$ -space with the induced diagonal action, let  $Y = \mathbb{C}P^3$  be the  $G$ -space with the action given by  $g \cdot [z_0 : z_1 : z_2 : z_3] = [gz_0 : gz_1 : gz_2 : gz_3]$  for  $g \in T$  and the involution  $\tau$  defined as the complex conjugation, then  $X^T \cong S^1 \times S^1$ ,  $X^\tau \cong S^0 \times S^0$ ,  $Y^T \cong \mathbb{C}P^1 \sqcup \mathbb{C}P^1$ ,  $Y^\tau \cong \mathbb{R}P^3$ . Notice that the induced  $T_2 \cong \mathbb{Z}/2$ -action on  $X^\tau$  is free while  $(Y^\tau)^{T_2} \cong \mathbb{R}P^1 \sqcup \mathbb{R}P^1$ .

Choose points  $x \in X^T \setminus X^\tau$  and  $y \in Y^T \setminus Y^\tau$ , then the orbit spaces  $G \cdot x \cong G \cdot y$  consist of two points and the stabilizers  $G_x \cong G_y \cong T$ . By the equivariant tubular neighborhood theorem (Theorem ??), there exist  $U \subseteq X$ ,  $V \subseteq Y$   $G$ -invariant neighborhoods of  $x$  and  $y$  respectively such that  $U \cong V \cong D^6 \times \mathbb{Z}/2$ ,  $T$  acts by scalar multiplication on the complex components of  $D^6 \subseteq (\mathbb{C} \times \mathbb{R})^2$  and  $\tau$  is the complex conjugation on  $D^6$  on the complex components, and multiplication by  $-1$  on the real components and the  $\mathbb{Z}/2$  factor. Let  $M$  be the space obtained as ‘‘a double connected sum’’ by removing  $U$  and  $V$  from  $X$  and  $Y$  respectively and gluing the spaces  $X \setminus U$  and  $Y \setminus V$  along a double cylinder  $I \times S^5 \times \mathbb{Z}/2$  where  $G$  acts trivially on the unit interval  $I$  and on  $S^5 \times \mathbb{Z}/2$  as the restriction of the action on the boundary of  $D^6 \times \mathbb{Z}/2$  described above. Note that  $M$  can be obtained by attaching a handle to the connected sum  $X \# Y$ . Therefore, from Lemma 2.8, the Betti numbers of  $M$  are 1, 1, 1, 2, 1, 1, 1 in degree 0, 1, ..., 6 respectively and thus  $b(M) = 8$ . We have also that  $M^T \cong M_0 \sqcup \mathbb{C}P^1$  where  $M_0$  is homeomorphic to a ‘‘double connected sum’’ between  $S^1 \times S^1$  and  $\mathbb{C}P^1$ , which is indeed homeomorphic to a genus 2 surface. Therefore,  $b(M^T) = b(M_0) + b(\mathbb{C}P^1) = 6 + 2 = 8$  so  $M$  is a  $T$  equivariantly formal space. Moreover, the symplectic form  $\Omega \in H^2(\mathbb{C}P^3)$  induces a c-symplectic form  $\omega \in H^2(M)$  which admits an equivariant lifting  $\tilde{\omega} \in H_T^2(M)$  and thus the action of  $T$  on  $M$  is c-Hamiltonian. On the other hand,  $M^\tau \cong (S^0 \times S^0) \sqcup \mathbb{R}P^3$  and thus  $b(M^\tau) = 4 + 4 = 8$ ; however,  $(M^\tau)^{T_2} \cong \mathbb{R}P^1 \sqcup \mathbb{R}P^1$  and  $b((M^\tau)^{T_2}) = 4$ , that is,  $M^\tau$  is not equivariantly formal with respect to the  $T_2$ -action.  $\square$

This example is a c-symplectic space which does not satisfy the weak Lefschetz condition, that is, the multiplication by  $\omega^2 : H^1(M) \rightarrow H^5(M)$  is clearly zero. Indeed, since  $H^3(M)$  is generated by the elements  $a, b \in H^3(S^3 \times S^3)$  and in the cohomology of the connected sum  $H^*(S^3 \times S^3 \# \mathbb{C}P^3)$  we have that  $a \cdot \omega = b \cdot \omega = 0$ , the same equation holds in the cohomology  $H^*(M)$ . This implies that for the generator  $x \in H^1(M)$  we have  $x \cdot \omega = \lambda_1 a + \lambda_2 b$  for some  $\lambda_1, \lambda_2 \in \{0, 1\}$  and thus  $x \cdot \omega^2 = 0$ .

In the case of c-Kähler spaces, any torus action with non empty fixed points is formal and thus c-Hamiltonian. This follows from this stronger result due to A. Blanchard [Blanchard, 1956, Thm. II.1.2].

**Theorem 2.11.** *Let  $X$  be c-Kähler space (over a field  $\mathbb{k}$ ) and  $X \rightarrow E \rightarrow B$  be a fiber bundle. Consider cohomology with coefficients over a field  $\mathbb{k}$ . Suppose that  $\pi_1(B)$  acts trivially in the cohomology  $H^*(F)$ , then the Serre spectral sequence collapses and*

$$H^*(E) \cong H^*(B) \otimes H^*(X).$$

As an immediate result, for any connected group  $K$  acting on  $X$ , if the fixed point subspace  $X^K \neq \emptyset$ ,  $X$  is  $K$ -equivariantly formal. Now we can prove Duistermaat’s theorem in the case of c-Kähler spaces.

**Proposition 2.12.** *Let  $X$  be a c-Kähler space (over  $\mathbb{k} = \mathbb{F}_2$ ) with an action of a torus  $T$  and a compatible anti-symplectic involution  $\tau$ . Assume that  $\tau$  acts trivially in the cohomology of  $X$ . Then  $X$  is  $T$ -equivariantly formal over  $\mathbb{k}$  and the real locus  $X^\tau$  is  $T_2$  equivariantly formal over  $\mathbb{k}$ .*

*Proof.* From Blanchard’s result, we have that  $X$  is  $T$ -equivariantly formal over  $\mathbb{k}$ . This implies that it is also  $T_2$ -equivariantly formal by Corollary ?? and so  $T_2$  acts trivially on the cohomology of  $X$ . By assumption,  $\tau$  acts trivially on the cohomology of  $X$  as well and thus the group  $H = T_2 \times \tau$  acts trivially in the cohomology of  $X$ . Using again Theorem 2.11 we obtain that  $X$  is  $H$ -equivariantly formal. Finally, the  $T_2$ -equivariant formality of the real locus  $X^\tau$  follows from Theorem ??  $\square$
